The Association Between PTSD and ADHD: Does the Association Reveal a PTSD-Somatoform Subtype?

To the Editor: Spencer et al1 recently published the findings of their meta-analysis in which they report a robust bidirectional association between attention-deficit/hyperactivity disorder (ADHD) and posttraumatic stress disorder (PTSD). One of the most peculiar results found by Spencer et al was that “the increased risk for PTSD in individuals with ADHD cannot be explained solely by an increased rate of trauma exposure in this population,” suggesting other environmental and biological factors may be involved.

Schottenfeld and Cullen2 discussed a PTSD subtype that may clinically present as a somatoform disorder and is quite likely attributable to hypersensitivity to certain occupational-induced exposures including air pollution (“All of the patients with atypical posttraumatic stress disorder attempted to avoid exposure to such odors, often by limiting work, hobbies, or other activities. One patient habitually wore a gas mask whenever she left her house”). Giacobo et al3 showed that subjects with ADHD exhibit functional somatic symptoms, suggesting that atypical PTSD may share some physiological similarities with diagnosed ADHD.

Geracioli et al4 demonstrated higher norepinephrine concentrations in the cerebrospinal fluid of male combat veterans versus healthy male controls, suggesting that a heightened central noradrenergic baseline may characterize typical PTSD pathology. Certain environmental exposures, though, may elicit similar neurologic effects as those found in typical PTSD and thus contribute to not only an atypical presentation of PTSD (ie, without trauma) but ADHD as well.

I have previously suggested that daily exposure to certain environmental air pollutants, principally nitrous oxide (N\textsubscript{2}O), may contribute to the development of neuropathology, including ADHD.5 Zhang et al6 reported that the analgesic action of N\textsubscript{2}O may contribute to the development of neuropathology, including ADHD.5

This discussion posits a neurobiological explanation for the association between PTSD and ADHD, as shown by Spencer et al in their meta-analysis. More work is needed to better characterize the nature of this association and the underlying physiological mechanisms and determine whether certain subtypes of the disorders (ie, atypical vs typical PTSD, hyperactive versus inattentive ADHD) are more closely associated than others.

Understanding these neurobiological interactions may be helpful for clinicians and scientists in their efforts to better monitor and treat patients with various presentations of the 2 disorders (typical PTSD, atypical PTSD with comorbid ADHD, etc).

Drs Spencer and Biederman Reply

To the Editor: We thank Mr Fluegge for his commentary on our recently published article. Our meta-analysis showed a robust and bidirectional association between ADHD and PTSD and included only studies that operationalized the diagnoses of ADHD and PTSD using standardized tools and DSM criteria. Therefore, our study did not address any connection between PTSD-like or ADHD-like symptoms that do not meet DSM criteria or that may be considered atypical presentations of either disorder. We also did not show a specific association with environmental toxins in our meta-analysis.

All subjects with PTSD had, by definition, experienced trauma. Trauma is necessary for the development of PTSD, but not all individuals who are traumatized develop PTSD. Our findings that the association between ADHD and PTSD was not fully explained by trauma indicate that among groups of people who have experienced similar trauma, those with ADHD are more likely to develop PTSD, and those who develop PTSD are more likely to have ADHD. The link we discovered was not between ADHD and trauma, but rather specifically between ADHD and the development of PTSD following a traumatic experience. This finding suggests that individuals with ADHD may have a vulnerability to developing PTSD following a traumatic experience and certainly warrants future investigation.
