Yuhei Kikuchi, MD^{a,b}; Yutaro Shimomura, MD^{a,c}; Takefumi Suzuki, MD, PhD^d; Hiroyuki Uchida, MD, PhD^a; Masaru Mimura, MD, PhD^a; and Hiroyoshi Takeuchi, MD, PhD^{a,*}

ABSTRACT

Objective: To compare efficacy and safety of single daily dosing (Single-DD) vs multiple daily dosing (Multiple-DD) regimens of psychotropic drugs, the authors conducted a systematic review and meta-analysis.

Data Sources: A systematic literature search of MEDLINE and Embase was conducted with keywords related to dosing regimens and psychotropic drugs (last search: December 30, 2019)

Study Selection: Randomized controlled trials comparing clinical outcomes between Single-DD and Multiple-DD of the same formulation of the same psychotropic drugs in patients with psychiatric disorders were included.

Data Extraction: Data on study discontinuation, psychopathology, and treatment-emergent adverse events (TEAEs) were extracted.

Results: A total of 32 studies with 34 paired comparisons involving 3,142 patients met the eligibility criteria and were included in the meta-analysis. Various types of psychotropic drugs were examined: antidepressants (22 comparisons), antipsychotics (7 comparisons), benzodiazepines (2 comparisons), mood stabilizers (2 comparisons), and antidepressantbenzodiazepine combination (1 comparison). There was no significant difference in study discontinuation due to all causes (30 comparisons, N = 2,883, risk ratio [RR] = 1.01, 95% CI = 0.94 to 1.09, P = .77), lack of efficacy (22 comparisons, N=2,307, RR=1.06, 95% CI=0.84 to 1.33, P=.62), or adverse events (25 comparisons, N=2,571, RR=0.93, 95% CI=0.75 to 1.14, P=.47) between the Single-DD and Multiple-DD groups. No significant difference was found in changes in psychopathology (8 comparisons, N = 1,337, standardized mean difference = 0.00, 95% CI = -0.11 to 0.11, P=.99) between the 2 groups. These results were also true for any type of psychotropic drugs. In terms of TEAEs, however, there were significant differences in anxiety (4 comparisons, N = 347, RR = 0.53, 95% CI = 0.33 to 0.84, P = .007) and sleepiness (3 comparisons, N = 934, RR = 0.82, 95%) CI = 0.68 to 0.99, P = .04) in favor of the Single-DD group.

Conclusions: The findings suggest Single-DD can be clinically adopted regardless of type of psychotropic drugs in patients with psychiatric disorders in general.

ow the dose of psychotropic drug is I fragmented within a day (ie, daily dosing regimen of psychotropic drug) is traditionally determined based on its peripheral elimination halflife. In general, product monographs and package inserts recommend that psychotropic drugs with a<24-hour half-life are to be administered in a divided dosing regimen (ie, multiple daily dosing [Multiple-DD] regimen) and those with $a \ge 24$ -hour half-life in a once-daily dosing regimen (ie, single daily dosing [Single-DD] regimen). However, realworld clinical practice indicates that this simple principle is not always followed. For instance, a cross-sectional survey showed that clozapine was prescribed in a once-daily dosing regimen in approximately 75% of patients in the United States and Canada, although the product monograph in both countries states that clozapine should be administered twice or 3 times a day.¹

Maintaining good adherence to medications is critically important to maximize their therapeutic effects,² and a simple drug regimen is advantageous from this viewpoint.³ The field of psychiatry is no exception; some past randomized controlled trials (RCTs) endeavored to compare efficacy and safety between Single-DD and Multiple-DD of various types of psychotropic drugs including antipsychotics,4-6 antidepressants,7-9 benzodiazepines,¹⁰⁻¹² antiepileptics,¹³ and lithium.¹⁴ To our knowledge, there have been only 2 meta-analyses that focused on this topic,^{15,16} suggesting that Single-DD is not inferior to Multiple-DD in terms of efficacy and acceptability; however, these meta-analyses only included RCTs of antidepressants and were published more than 15 years ago. To address this clinically important question, we conducted a systematic review and meta-analysis of RCTs comparing Single-DD and Multiple-DD of all types of psychotropic drugs for psychiatric disorders.

METHODS

Literature Search and Study Selection

We conducted a systematic literature search in accordance with the Preferred Reporting Items

It is illegal to post this copyrighted PDF on any website.

Clinical Points

- This meta-analysis included 32 randomized controlled trials comparing clinical outcomes between single and multiple daily dosing regimens of the same formulation of the same psychotropic drugs in patients with psychiatric disorders.
- No significant differences were found in study discontinuation or psychopathology between single and multiple daily dosing regimens, while there were significant differences in anxiety and sleepiness in favor of a single daily dosing regimen.
- A single daily dosing regimen can be a viable option regardless of psychotropic types in patients with psychiatric disorders in general.

for Systematic Reviews and Meta-Analyses (PRISMA) statement¹⁷ to identify RCTs comparing Single-DD and Multiple-DD regimens of all types of psychotropic drugs for psychiatric disorders (last search: December 30, 2019). To this end, MEDLINE and Embase were searched with the following keywords: (((once[ti] OR twice[ti] OR thrice[ti]) AND (daily[ti] OR day[ti])) OR ((dosing[ti] OR dose*[ti] OR dosage*[ti]) AND (regimen*[ti] OR schedule*[ti] OR single[ti] OR multiple[ti] OR divided[ti] OR split[ti] OR qd[ti] OR quaque die[ti] OR qhs[ti] OR quaque hora somni[ti] OR bid[ti] OR bis in die[ti] OR tid[ti] OR ter in die[ti]))) AND (psychotropic* OR antipsychotic* OR antidepressant* OR lithium OR divalproex OR valpro* OR lamotrigine OR carbamazepine OR mood stabilizer* OR benzodiazepine* OR antianxi* OR hypnotic*). We also searched CENTRAL using the same keywords to check if we had missed any other literature and conducted a hand search. Two authors (Y.K. and Y.S.) independently selected studies that met the following inclusion criteria: an RCT comparing clinical outcome(s) between Single-DD and Multiple-DD of the same formulation of the same psychotropic drugs(s) in patients with psychiatric disorder(s). Literature reported in languages other than English was excluded. Any disagreements about the study selection were resolved by consensus with 2 authors (Y.K. and Y.S.) under the supervision of the senior author (H.T.).

Two authors (Y.K. and Y.S.) independently assessed risk of bias for the selected studies according to the Cochrane Handbook for Systematic Reviews of Interventions (available at http://handbook.cochrane.org). Any disagreements about the assessment were resolved by consensus with 2 authors (Y.K. and Y.S.) under the supervision of the senior author (H.T.).

Data Extraction

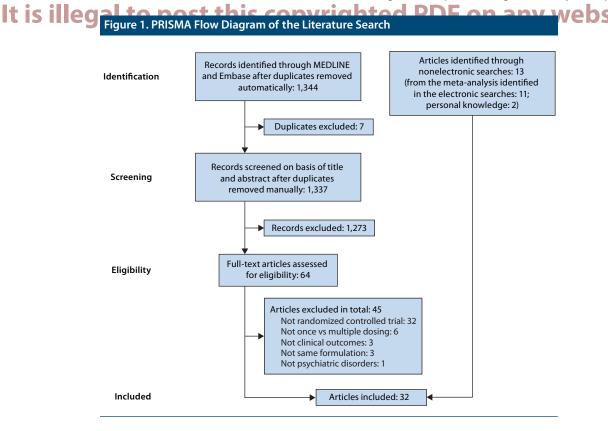

Two authors (Y.K. and Y.S.) independently extracted the following clinical outcome data in both Single-DD and Multiple-DD groups from the selected studies: (1) the number of patients who discontinued the study due to all causes, lack of efficacy, and adverse events; (2) the mean \pm SD of changes in scores on primary (3) the number of patients who experienced treatmentemergent adverse events (TEAEs) that were reported in \geq 3 out of the identified comparisons. Because there were variants in expression of TEAEs, we combined those that were considered a synonymous term. Two studies included 2 Single-DD regimens (ie, at night and in the morning)^{18,19}; we used the data in the night group. Also, 1 study included 2 Multiple-DD regimens (ie, twice and 3 times daily dosing)²⁰; we used the data in the twice daily dosing group. We employed WebPlotDigitizer (available at https://automeris. io/WebPlotDigitizer/) if the included studies provided only graphs for the data. Any disagreements about the data extraction were resolved by consensus with 2 authors (Y.K. and Y.S.) under the supervision of the senior author (H.T.). If the selected studies provided insufficient data, we contacted the corresponding authors to obtain additional information necessary for the meta-analyses.

Data Analysis

We performed meta-analyses using Review Manager (RevMan) version 5.3 (The Nordic Cochrane Center, The Cochrane Collaboration; Copenhagen, Denmark; 2014). Outcome data were combined and compared between the Single-DD and Multiple-DD groups. For dichotomous and continuous outcomes, pooled estimates of risk ratios (RRs) and standardized mean differences (SMDs), respectively, were calculated with 2-sided 95% confidence intervals (CIs) using a random-effects model. Study heterogeneities were quantified using I^2 statistic with $I^2 \ge 50\%$ indicating significant heterogeneity. All effect sizes with a P < .05were considered significant. Two authors (Y.K. and Y.S.) independently performed the meta-analyses. Any disagreements about the meta-analyses were resolved by consensus with 2 authors (Y.K. and Y.S.) under the supervision of the senior author (H.T.).

As sensitivity analyses, we separately analyzed the following sets of studies: (1a) double-blind studies; (1b) non-double-blind studies; (2a) studies adopting intention-to-treat analysis; (2b) studies adopting modified intention-to-treat analysis; (2c) studies adopting completer analysis; (3a) studies examining psychotropic drugs with peripheral elimination half-life < 24 hours; (3b) studies examining psychotropic drugs with peripheral elimination half-life \geq 24 hours; (4a) studies examining psychotropic drugs with the description in the product monograph that the drug should be administered once daily (ie, Single-DD); and (4b) studies examining psychotropic drugs without the description in the product monograph that the drug should be administered once daily (ie, Single-DD).

We further repeatedly performed these analyses in studies examining once vs twice or once vs 3 times daily dosing. One study included twice daily and 3 times daily dosing groups²⁰; we used the data in the twice daily and 3 times daily dosing groups for the main analyses and the sensitivity analyses for studies examining once vs 3 times daily dosing, respectively.

RESULTS

Included Studies

A total of 32 studies published from 1974 to 2015 involving 3,142 patients (N = 1,598 and N = 1,544 for the Single-DD and Multiple-DD groups, respectively) that met our inclusion criteria were identified (Figure 1).4-14,18-38 Only 7 studies were published after 2000. As 2 studies included 2 separate comparisons, a total of 34 comparisons were included in the meta-analysis. The characteristics of the eligible studies are summarized in Table 1. Among the 32 studies, 23, 1, and 5 were conducted in a double-blind, rater-blind, and openlabel fashion, respectively. Various types of psychotropic drugs were examined: antidepressants (22 comparisons), antipsychotics (7 comparisons), benzodiazepines (2 comparisons), mood stabilizers (2 comparisons), and antidepressant-benzodiazepine combination (1 comparison). The Multiple-DD group included 3 types of regimens: twice daily dosing (17 comparisons), 3 times daily dosing (16 comparisons), and 4 times daily dosing (1 comparison). The authors of 5 studies provided additional data.4,6,8,14,38 The dose was fixed in 19 comparisons (ie, same doses for both groups), while the dose was flexible in 9 comparisons; the mean dose at the endpoint was lower and higher in the Single-DD group than the Multiple-DD group in 8 and 1 comparisons, respectively.

The results of risk of bias assessment are described in Supplementary Figure 1. The risks of random sequence generation and of allocation concealment were unclear in all of the studies. The risk of incomplete outcome data was high in general, because older studies adopted completer analysis.

Study Discontinuation

There was no significant difference in study discontinuation due to all causes (30 comparisons, N=2,883, RR=1.01, 95% CI=0.94 to 1.09, P=.77), lack of efficacy (22 comparisons, N=2,307, RR=1.06, 95% CI=0.84 to 1.33, P=.62), or adverse events (25 comparisons, N=2,571, RR=0.93, 95% CI=0.75 to 1.14, P=.47) between the Single-DD and Multiple-DD groups of all psychotropic drugs (Figure 2). Moreover, no significant difference in any study discontinuation was found between the 2 groups in any subgroup of antidepressants, antipsychotics, benzodiazepines, mood stabilizers, and antidepressant-benzodiazepine combination.

Psychopathology

No significant difference was found in score changes on psychopathology scales (8 comparisons, N=1,337, SMD=0.00, 95% CI=-0.11 to 0.11, P=.99) between the Single-DD and Multiple-DD groups (Figure 3). There was no significant difference between the 2 groups in any subgroup of antidepressants, antipsychotics, and mood stabilizers, although caution is necessary as data were relatively scarce for psychopathology, because older studies frequently failed to provide standard deviation or standard error.

Treatment-Emergent Adverse Events

A total of 35 types of TEAEs were included in the meta-analysis. There were significant differences between the Single-DD and Multiple-DD groups in anxiety (4 comparisons, N = 347, RR = 0.53, 95% CI = 0.33 to 0.84, P = .007) and sleepiness (3 comparisons, N = 934, RR = 0.82, 95% CI = 0.68 to 0.99, P = .04), both in favor of the Single-DD

group (Figure 4). The same results were found in the subgroup of antipsychotics.

Sensitivity Analyses

While there were no significant differences in any study discontinuation or psychopathology between the Single-DD and Multiple-DD groups in any sensitivity analyses

It is illocal to post this convrighted PDE on any website Figure 2 (continued).

(Supplementary Table 1), some significant differences in TEAEs were found between the 2 groups in some sensitivity analyses (Supplementary Table 2). Overall, anxiety and sleepiness were favorable in the Single-DD group, while a couple of items including dizziness and drowsiness were in favor of the Multiple-DD group in some sensitivity analyses.

DISCUSSION

The current meta-analysis revealed no significant differences in all-cause study discontinuation, discontinuation due to lack of efficacy as well as adverse events, or changes in psychopathology between Single-DD and Multiple-DD regimens of both all and individual types of psychotropic drugs. In terms of TEAEs, however, there were significant differences in anxiety and sleepiness in favor of Single-DD regimen. The findings corroborate the previous meta-analyses focusing on antidepressants,^{15,16} but the advantage of our meta-analysis is that all types of psychotropic drugs were included.

Although dosing interval of a psychotropic drug is generally determined according to its peripheral elimination half-life, our meta-analysis found no superiority for Multiple-DD over Single-DD, regardless of the half-lives

of the compounds. The dosing frequency is associated with medication adherence and is reasonably a topic of scrutiny; a systematic review showed that less frequent dosing is plausibly related to better medication adherence in chronic psychiatric diseases.⁴¹ In addition, a meta-analysis found that patients receiving Single-DD were more adherent than those receiving Multiple-DD in chronic diseases,⁴² and another meta-analysis of 4 RCTs indicated that Single-DD was associated with a lower risk of nonadherence than

Multiple-DD in chronic cardiovascular disease.⁴³ Although Single-DD may facilitate adherence to psychotropic drugs, thereby improving long-term outcomes in chronic conditions, the current meta-analysis was not able to address this clinically important question. In the current meta-analysis, only 6 included RCTs measured medication adherence as a clinical outcome^{4,6,13,29,35,38}; 5 studies reported no significant difference between the Single-DD and Multiple-DD groups, and 1 study found superiority in

Kikuchi et al

It is illegal to post this copyr the Single-DD group. Nevertheless, because these 6 studies did not provide sufficient data, we were not able to perform a meta-analysis. Moreover, medication adherence was variably assessed. Further RCTs are urgently needed to examine the effects of Multiple-DD vs Single-DD of psychotropic drugs on medication adherence as well as on long-term clinical consequences including psychopathology, functioning, and subjective well-being.

The finding of no difference in efficacy between Single-DD and Multiple-DD of psychotropic drugs may be supported by neuroimaging studies. In terms of antipsychotics, for instance, a recent systematic review of studies using positron emission tomography (PET) or single-photon emission computed tomography indicated that pharmacokinetic attenuation of antipsychotics was generally slower at the central level than the peripheral level.⁴⁴ As for antidepressants, 2 studies using PET reported that duloxetine, escitalopram, and sertraline showed a sustained time-course of serotonin transporter occupancy compared to the plasma concentrations.^{45,46} Given that the PET studies have been consistent in showing that pharmacokinetics of at least some psychotropic drugs are substantially slower centrally than peripherally, drugs that affect the central nervous system may be administered once daily irrespective of the peripheral elimination halflife of the compound. Nonetheless, further investigations are necessary on this issue, and due caution is necessary because there are no neuroimaging studies examining other psychotropic drugs such as benzodiazepines on this topic, possibly due to a lack of good tracers.

Contrary to the findings on efficacy, the current metaanalysis indicated that Single-DD of psychotropic drugs was found to be superior to Multiple-DD in terms of anxiety and sleepiness. It is not clear why Single-DD was associated with less anxiety, although 1 included study speculated that higher peak plasma drug concentrations in Single-DD than Multiple-DD contributed to a greater degree of amelioration of anxiety.³⁶ The superiority of Single-DD for sleepiness may be due to a more sedative effect during daytime in Multiple-DD. Indeed, 1 study reported that oral risperidone caused sedation more frequently a few hours after administration than at 24 hours,⁴⁷ and another study reported that intramuscular olanzapine caused more sedation 2 hours after administration than at 24 hours.⁴⁸ If a patient is taking psychotropic drug(s) in Multiple-DD and is suffering from sleepiness and/or anxiety, switching to Single-DD would be a reasonable treatment strategy.

There are several limitations to be noted. First, the data on psychopathology and individual TEAEs were available for only 8 and up to 5 comparisons, respectively, which may have resulted in insufficient statistical power. Second, the current meta-analysis was associated with a high attrition bias, because the vast majority of the included studies were conducted in 1970s and 1980s, adopted the completer analysis method, and were associated with a high attrition rate; half of the studies were judged to have a high risk for incomplete outcome data. As 1970s and 1980s studies included in the meta-analysis examined relatively older antidepressants and benzodiazepines, the findings may not be generalizable to more recent psychotropic agents that are currently more widely utilized. Third, our metaanalysis did not cover all types of psychotropic drugs or psychiatric disorders; for example, no RCTs examining psychostimulants or antidementia drugs were found through our systematic literature search. Fourth, approximately two thirds of the studies did not provide such information, and we were unable to know if these studies examined efficacy of initiating a new drug in Single-DD vs Multiple-DD, switching Multiple-DD to Single-DD for an ongoing drug vs continuing Multiple-DD, or switching Single-DD to Multiple-DD for an ongoing drug vs continuing Single-DD. Fifth, the information on concomitant drugs that could have influenced the results was not sufficiently provided: no concomitant drugs (1 comparison), no psychotropic concomitant drugs (2 comparisons), benzodiazepines and antiparkinsonians allowed (13 comparisons), any drugs allowed (4 comparisons), and no information (14 comparisons). Sixth, no studies reported factors that could affect drug metabolism, such as smoking and metabolizer status. Finally, as previously stated, actual medication adherence has rarely been addressed, and long-term clinical consequences of Single-DD vs Multiple-DD are largely unknown. Further RCTs with various types of psychotropic drugs for diverse psychiatric disorders are needed to confirm the present findings.

In conclusion, the current meta-analysis showed no difference in effectiveness or efficacy between Single-DD and Multiple-DD regimens of psychotropic drugs, regardless of the type of drugs, in patients with psychiatric disorders. Nonetheless, given the superiority of Single-DD over Multiple-DD for tolerability and given its simplicity, Single-DD warrants serious clinical consideration, in particular for patients who suffer anxiety and/or sleepiness or are at risk of suboptimal medication adherence.

- Article Title: Single Versus Multiple Daily Dosing Regimens of Psychotropic Drugs for Psychiatric Disorders: A Systematic Review and Meta-Analysis
- Author(s): Yuhei Kikuchi, MD; Yutaro Shimomura, MD; Takefumi Suzuki, MD, PhD; Hiroyuki Uchida, MD, PhD; Masaru Mimura, MD, PhD; and Hiroyoshi Takeuchi, MD, PhD
- **DOI Number:** 10.4088/JCP.20r13503

List of Supplementary Material for the article

- 1. Figure 1 Risk of Bias
- 2. <u>Table 1</u> Study Discontinuation and Psychopathology in Sensitivity Analysis
- 3. <u>Table 2</u> Treatment-Emergent Adverse Events With Significant Difference in Sensitivity Analysis
