# 1. Modelling the clinical progression of schizophrenia

The model compares a cohort unaffected by schizophrenia (general US population) with a cohort with schizophrenia from the age of 23 years, over an 80-year time horizon. The disease progression model simulates individuals' response to six sequences of antipsychotic treatments (Table 1). The average of all sequences of antipsychotics (AP) is finally used to predict the proportion of people with schizophrenia in remission or relapse.

Seq.	First line AP	Second Line AP	Third line AP	Long-term treatment <sup>a</sup>	
1	Quetiapine	Aripiprazole			
2	Aripiprazole		Average oral AP	(40.0%) No treatment (46.8%) Average oral APs	
3	Risperidone	Quetiapine			
4	Olanzapine			(10.1%) Average LAIS	
5	Lurasidone			(3.1%) Clozapine	

Table 1 – Antipsychotic sequences used in the model

#### Acronyms: AP, antipsychotic, LAI, Long-acting injectable antipsychotics

The AP agent with the highest market share utilization, not used as first-line treatment, was selected as second-line agent. The market shares used to establish treatment sequences and calculate the average efficacy and safety for oral APs were: 34.0% quetiapine, 18.0% aripiprazole, 16.0% risperidone, 12.0% olanzapine and 4.0% lurasidone.<sup>1</sup> The market shares used to calculate the average efficacy and safety for LAIs were: 66.0% paliperidone LAI, 29.3% risperidone LAI, 3.3% aripiprazole LAI, and 1.5% olanzapine LAI.<sup>2</sup>

<sup>a</sup> On the long-term 40.0% of people were assumed not to receive any treatment for schizophrenia. <sup>3</sup> The distribution long-term AP treatments was informed by Medicaid data. <sup>2</sup> Bareis and colleagues reported that 85.5% of patients would receive an AP (any), 14.4% LAIs, and 4.4% clozapine. These proportions were rearranged to be expressed as a proportion of the 60% receiving AP treatment (i.e., 60.0%\*[85.5%-14.4%-4.4%]/85.5%=46.8%).

#### 1.1. Antipsychotic drugs efficacy and safety

#### 1.1.1 Short-term antipsychotic use

The probabilities of discontinuing during the trial period were calculated from the rates of all cause discontinuation reported by published randomized controlled trials (RCTs) assessing the efficacy of oral APs. The likelihood of stable disease (remission) was calculated as 1 minus the probability of all cause discontinuation. The mean weight gain related to each AP was also obtained from published RCTs. The probabilities of unstable disease and mean weight gain used in the model are shown in Table 2 (trial period).

Table 2 – Probability of unstable disease and mean weight gain during the trial period, adjusted for 6-week cycle length

Antipsychotic agent	Probability of discontinuation <sup>a</sup>	Sources	Mean weight gain (Kg)	Sources
Quetiapine	0.417	4-16	1.644	4-11 15 17
Aripiprazole	0.328	7 8 16 18-30	0.692	8 18-20 23 25-27 29
Risperidone	0.304	8 13 15 16 19 25 27 29 31-45	1.930	8 15 19 25 27 29 30 32 40-42 46 47
Olanzapine	0.266	8 13 21 22 24 32 34 48-66	2.346	8 17 32 34 49 51 53-67
Lurasidone	0.337	11 36 39 59 68-73	0.491	11 39 59 68-73

<sup>a</sup> Defined as treatment inefficacy, occurrence of intolerable adverse effects (AE), or treatment discontinuation due to patient's decision at the end of the trial period. The probability of relapse was defined as one minus the probability of all cause discontinuation. It is likely that several sequences are used in clinical practice so efficacy and safety estimates for an average AP drug were calculated using arithmetic means, weighted according to the market shares for quetiapine, aripiprazole, risperidone, olanzapine, and lurasidone.<sup>1</sup>

The probability of unstable disease (relapse) and mean weight gain in people receiving maintenance therapy was sourced from an US cost-effectiveness analysis evaluating the use of atypical AP in the treatment of schizophrenia.<sup>74</sup> The likelihood of hospitalization was used as a proxy for the probability of unstable disease. The inputs utilized in the model are shown in Table 3.

Table 3 – Probability of unstable disease and mean weight gain during the maintenance period, adjusted for 6-week cycle length

	Antipsychotic agent	Probability of relapse	Mean weight gain (Kg)
--	---------------------	------------------------	-----------------------

Quetiapine	0.123	0.315
Aripiprazole	0.118	0.238
Risperidone	0.097	0.252
Olanzapine	0.075	1.259
Lurasidone	0.084	0.081
Clozapine	0.053	0.315

Source: O'Day 2013 74

The literature search strategy used to identify RCT evidence of the efficacy and safety of APs and the PICOS strategy detailing the inclusion criteria are presented in subsequent sections.

#### 1.1.2 Long-term antipsychotic use

Individuals presenting with active disease, despite third-line AP therapy, entered the long-term phase of the model. The distribution of individuals across long-term treatments is depicted in Table 1. People receiving AP treatment were assumed to achieve stable disease, being at risk of relapse. On the long-term, the efficacy and safety of oral APs were calculated as the average of individual APs effects during maintenance phase<sup>74</sup> (Table 3), weighted according to their US market shares.<sup>1</sup> Evidence informing the efficacy and safety of clonidine was also sourced from the cost-effectiveness study by O'Day et al.<sup>74</sup>

Evidence of the efficacy and safety of LAIs was sourced from a network meta-analysis (NMA) of APs.<sup>75</sup> The efficacy of LAIs was reported as pooled odds ratios (OR) compared to placebo. It was assumed that placebo would be a proxy for no treatment and that 74.1% <sup>76</sup> of all untreated individuals would present with active disease. Odds ratios were rearranged to relative risks (RR) using Equation 1<sup>77</sup> before being applied to the baseline probability of being in active disease.

$$RR = \frac{OR}{\left(1 - p_0 + (p_0 * OR)\right)}$$
Equation 1

Where  $p_0$  is the baseline probability of the event.

Evidence for 4 LAIs was selected for use in the model (paliperidone LAI, risperidone LAI, aripiprazole LAI, and olanzapine LAI) matching the availability of US market shares for LAIs identified in the literature.<sup>78</sup> The odds ratios of unstable disease and mean weight gain associated with LAIs use is shown in Table 4.

Table 4 – Odds ratios	of unstable disease	and mean w	veiaht aain d	associated to	lona-term	use of LAIs
	of anotable abcase a		cigine gain a		ong term	450 01 01 115

Antipsychotic agent	OR, relapse vs placebo	Mean weight gain (Kg) ª
Aripiprazole LAI	0.690	-0.032
Olanzapine LAI	0.160	0.291
Paliperidone LAI	0.300	0.171
Risperidone LAI	0.100	0.279

#### <sup>a</sup> Cycle-adjusted.

#### 1.2. Search Strategy

The OVID platform was used to conduct searches in the following literature databases: EMBASE, MEDLINE, including MEDLINE (R) In process, MEDLINE Epub Ahead of Print, In-Process & Other Non-Indexed Citations, MEDLINE Daily, Medline and Versions, Cochrane Central Register of Controlled Trials (CENTRAL) and PSYcINFO. Searches were conducted from inception to September 4<sup>th</sup>, 2020. The search strategy was based on the combination of free text words, indexing terms (e.g. Excerpta Medica database [EMBASE] subject heading [EMTREE] or Medical Subject Headings [MESH] terms) and their relationship using Boolean terms (e.g. 'and', 'or', 'not'). Full search strategies are specified in Table 5.

#### Table 5 – Literature search strategy

#	Searches

4	3 not ('case report' or 'case reports' or editorial or comment).ti,pt,xs,sh.
5	limit 4 to English language
6	De-duplicate

In addition, the following relevant conference websites were searched to identify relevant abstracts accepted at the most recent meeting only (abstracts from prior meetings were indexed in Ovid):

- 1. International College of Neuropsychopharmacology
- 2. American Psychiatric Association
- 3. U.S. Psychiatric & Mental Health
- 4. American Society of Clinical Psychopharmacology
- 5. American College of Neuropsychopharmacology
- 6. European College of Neuropsychopharmacology
- 7. European Congress of Psychiatry
- 8. European Psychiatric Association
- 9. Neuroscience Education Institute
- 10. Schizophrenia International Research Society (SIRS)

Bibliographies of up to three recent reviews on the efficacy and safety of atypical antipsychotics and LAIs in schizophrenic patients were cross-checked to identify additional studies.

Clinicaltrials.gov was consulted to search for any information that could be missing from the primary publication. No search was performed on clinicaltrials.gov for trial identification.

#### 1.3. Eligibility criteria and study selection

The publications identified by the literature search were sifted by 2 researchers based on titles and abstracts according to pre-established criteria (Table 1). Full papers were then inspected and considered for inclusion. Data extraction was conducted by a single reviewer.

Table 6 – PICOS strategy

PICOS	Inclusion Criteria	Exclusion Criteria
Population	Adults (>= 18 years) and adolescents with schizophrenia	<ul> <li>Studies with patients who do not have schizophrenia</li> <li>Pregnant</li> </ul>
Intervention	<ul> <li>SGAs<sup>a</sup> approved in the US or Europe and new experimental treatments as monotherapy or their combination</li> <li>Oral treatment</li> <li>Long-acting injectables</li> </ul>	<ul> <li>Interventions that are not SGAs</li> <li>Studies with no pharmacological therapy</li> </ul>

			notes, commentaries, reviews

Acronyms: RCTs, randomized controlled trials; SGAs, second-generation antipsychotics; US, United States

<sup>a</sup> SGAs approved in the United States and Europe only at the approved doses will be included. For newer experimental treatments not yet approved, all doses will be included.

Antipsychotic-specific outcomes for the probability of unstable disease and weight gain were calculated using arithmetic averages weighted by study sample size. The resulting estimates were used as absolute probabilities in the model. This simplified approach was preferred (to indirect treatment comparison) because the main goal of the evidence review was to calculate the efficacy and safety of an AP therapy (representative of AP with largest market share), rather than comparing one AP or sequence of APs to another.

#### 1.4. Mortality

Mortality was modelled using a lifetable method based on annual mortality rates published by Arias and Xu.<sup>79</sup> The annual mortality rates due to suicide or due to cardiovascular disease in the general population were disaggregated from overall mortality using age and gender specific US prevalence figures for suicide and CVD-related mortality.<sup>80</sup> The resulting risk of suicide was multiplied by published standardized mortality ratios (SMR) in males (SMR 3.39 standard error [SE] 0.03) and females (SMR 8.16, SE 0.04) to derive the increased risk of suicide in the schizophrenia population.<sup>81</sup>

The baseline risk of a cardiovascular event was estimated using the Framingham risk equations featuring body mass index (BMI) predictors.<sup>82 83</sup> The likelihood of death after a cardiovascular event was sourced from a US publication reporting the case fatality rate in individuals having cardiovascular events.<sup>84</sup> The input used in the model (9.5%) was calculated as the weighted average of the case fatality rate amongst people having a myocardial infarction, cardiac arrest, and ischemic or hemorrhagic stroke.

#### Cardiovascular risk covariates

Gender, age, BMI, systolic blood pressure (SBP) in treated or untreated, diabetes and smoking status covariates were required to inform the Framingham equations. Age and sex were obtained from the progressing model cohort. The remaining inputs were sourced from the literature and are shown in Table 7.

BMI was calculated as the weight in kilos divided by the squared height in centimeters. The height and weight for males and females at the start of the model (30 years) was sourced from average age-specific values from the general US population.<sup>85</sup> The same values were used for the population with schizophrenia. Weight gain due to AP use was modelled in the schizophrenia cohort using efficacy and safety data from trial and maintenance periods APs (Table 2 and Table 3). To avoid indefinite weight increase in people receiving AP therapy, a cutoff point of 7% increase from baseline weight was implemented in the model. It was assumed that people would not return to baseline body weight.

The distribution and SBP values for individuals with normal blood pressure or with hypertension on/off treatment were sourced from US health statistics.<sup>86</sup> The age specific prevalence of diabetes in the group unaffected by schizophrenia was informed by general US population data.<sup>87</sup> The likelihood of diabetes in the schizophrenia population was estimated by adjusting the US population prevalence values using an odds ratio (OR 1.83, 95% CI 1.29 to 2.60) sourced from an US study comparing 326 individuals with schizophrenia or schizoaffective disorder to 1,899 controls.<sup>88</sup> The prevalence of smoking in the general population used US age and gender specific data.<sup>89</sup> The excess likelihood of smoking in people with schizophrenia was informed by a meta-analysis studying the association between schizophrenia and tobacco use (OR 5.30, 95% CI 4.90 to 5.70).<sup>90</sup> Before being applied to the general population values, the ORs were converted to relative risks (RR) using Equation 1.<sup>77</sup>

Description	Males	Females	SE	Source
Risk of death from a cardiovascular event	9.5	5% a	20% of mean	84

Table 7 – Mean inputs informing cardiovascular risk factors in the model

Acronyms: OR, odds ratio; SE, standard error; SBP, systolic blood pressure; US, United States.

<sup>a</sup> Weighted average of the case fatality rates for myocardial infarction, cardiac arrest, and ischemic or hemorrhagic stroke.

<sup>b</sup> Applied to the prevalence of smoking in the general population to derive the likelihood of smoking in people with schizophrenia.

## 2. Modelling transitions between social states

#### 2.1. Incarceration

Age and gender adjusted lifetime probabilities of incarceration in prisons for the adult US general population were sourced from a publication by the Bureau of Justice Statistics.<sup>91</sup> These probabilities were annualized using Equation 2.

$$p = 1 - exp\left(\frac{ln(1-p_i)}{t_i} * t\right)$$
 Equation 2

where  $p_i$  is the age and gender specific index probability,  $t_i$  the index time calculated as the maximum for the age category minus the minimum age of incarceration (18 years), and t is the cycle length. The maximum age at which individuals would be incarcerated was implemented as 70 years as based on a publication by US Department of Justice.<sup>92</sup> The number of incarcerations in jails were estimated by multiplying these probabilities by a ratio of jail to prison incarceration. The ratio (0.540) was obtained by dividing the proportion of individuals sentenced to jails (33.5% [738,400/2,203,600]) by the proportion of individuals sentenced to prisons (66.5% [1,465,200/2,203,600]) in 2019.<sup>93</sup>

The probability of incarceration in people with schizophrenia was obtained by multiplying the probability of incarceration in the general population by the relative risk (RR) of incarceration in people with schizophrenia. Different RR were calculated to translate the likelihood of incarceration in prisons (3.99) or jails (5.93). These RRs were calculated by dividing the prevalence of incarceration in the US general adult population (0.9% [2,123,100/255,200,373]) by the prevalence of schizophrenia in US prisons. The prevalence of schizophrenia in US prisons was calculated by averaging the values reported by a systematic review of US studies.<sup>94</sup> Due to heterogeneity in the values reported by Prins and colleagues, we ran a scenario using calculated values for the prevalence of schizophrenia in US prisons (8.7% [125,437/1,441,800]) <sup>95</sup> or US jails (11.70% [84,263/720,200]).<sup>95</sup> The prevalence estimates reported by Bronson and Berzofsky <sup>95</sup> considered inmates with schizophrenia and other psychotic disorders in prison and jail. These estimates were adjusted using the proportion of people with schizophrenia amongst the population with schizophrenia and other psychotic disorders (46.1%).<sup>96</sup>

The time dependence associated to varying durations of incarceration reported in the literature were accounted for by implementing a series of tunnel states (20 for prisons and 6 for jails).<sup>97 98</sup> After being released, individuals entered a sequence of 5 ex-convict tunnel states to account for the increased likelihood of reincarceration in this population.<sup>99</sup> When ex-convicts returned to the community state, the model was no longer able to determine if they were ever incarcerated.

The higher probability of incarceration in homeless people was implemented by multiplying the probability of incarceration for community dwelling individuals by the relative risk of incarceration in the homeless (9.03). This ratio was calculated by dividing the proportion of individuals in jail who were homeless (15.3%) by the annual rate of homelessness in the general population (1.7%), both sourced from a survey of 6,953 US jail inmates.<sup>100</sup>

Incarceration rate ratios for individuals in remission or relapse versus the general schizophrenia population were calculated by dividing the cumulative incidence of arrests in people with remission or relapse by the cumulative incidence of arrests in the entire sample of people with schizophrenia, as reported in the US longitudinal study conducted by Haynes and colleagues.<sup>101</sup> Arrest does not mandate incarceration, nonetheless the likelihood of arrest was perceived as a reasonable proxy for incarceration, as it implies a level of offense punishable by law. All inputs related to the likelihood and duration of (re)incarceration are available in Table 8.

Table 8 - Inputs informing the likelihood and duration of (re)incarceration

RR of going to prison (schizophrenia vs US population)		3.99	Not varied	Calculated
RR of going to jail (schizophrenia vs US population)		5.93	Not varied	Calculated
Incarceration in the homeless population				
Proportion of individuals in jail who were homeless		15.3%	200/	100
Annual rate of homelessness in general population		1.7%	20% of mean	
RR incarceration in homeless vs general US population		9.03		Calculated

Acronyms: RR, relative risk; SE; standard error; US, United States

<sup>a</sup> The lifetime probabilities of incarceration were annualized based on the published probabilities using Equation 2. The period for the rate was calculated by subtracting the minimum age of incarceration (18 years) by the upper age in the age category i.e., 35 to 44 years category, 45-18=27 years; 25 to 34 years category, 35-18=17 years.

<sup>b</sup> Considered to be the same in the general population and in people with schizophrenia.

<sup>c</sup> Used in scenario analysis.

#### 2.2. Homelessness

The inputs utilized to inform transitions to the homeless social state and homelessness recurrence are shown in Table 9. The age adjusted annual probabilities of homelessness were calculated by multiplying the prevalence of homelessness in the general population by the age distribution of sheltered individuals in one year (October 2009 to September 2010).<sup>103</sup> The prevalence of homelessness in the general population (0.7%) was calculated by dividing the number of individuals experiencing homelessness in one year in 2010 (1,593,150)<sup>103</sup> by the total US population in 2010 (234,564,071).<sup>104</sup>

The probability of homelessness in people with schizophrenia was implemented by multiplying the probability of becoming homeless in the general US population by the relative risk of homelessness in the schizophrenia populations. The relative risk of homelessness in the population with schizophrenia (15.55) was calculated by dividing the prevalence of schizophrenia in the homeless population (10.6%)<sup>105</sup> by the prevalence of homelessness in the general population (0.7%).

Table 9 – Inputs informing the likelihood of (repeated) homelessness

Description	Input	SE	Source
Homelessness in the general US population

Homelessness in people with schizophrenia			
Prevalence of schizophrenia in homeless population	10.6%	2.5%	105
RR of homelessness vs general population	15.55		Calculated
RR of homelessness after previous shelter use	8.33	0.152	107
RR of homelessness in ex-convicts with mental illness	2.47	0.18	

Acronyms: RR, relative risk; SE, standard error; US, United States.

The rate ratios of the likelihood of homelessness for those in remission or relapse were calculated using Adelphi real-world data <sup>108</sup> (Table 11). These ratios were multiplied by the cycle probability of homelessness in the general schizophrenia population, so that the estimates were adjusted to individuals' remission or relapse status.

There is evidence suggesting that ex-convicts have a higher risk of homelessness, compared to the general population. In the general population, the probability of homelessness after release from incarceration used annualized age specific values published by Metraux.<sup>109</sup> Remster and colleagues <sup>107</sup> suggested that ex-convicts with mental illness were approximately 2.47 times more likely to become homeless, compared to the ex-convicts without mental illness. Therefore, this estimate was multiplied by the general population probabilities to obtain the probabilities in the cohort with schizophrenia.

The probability of returning to homelessness was informed by an US publication suggesting that individuals who had been sheltered before had 8.3 higher risk of experiencing homelessness again versus the general population.<sup>107</sup> This estimate was multiplied by the probability of homelessness in the general population or in the schizophrenia cohort to obtain the annual probability in ex-homeless individuals.

# 3. Likelihood of fiscal consequences

Costs were linked to fiscal consequences to generate total costs for people with and without schizophrenia. Due to the lack of schizophrenia-specific data we assumed that the annual healthcare costs per capita for homeless people with or without schizophrenia would be the same.

#### 3.1. Fiscal consequences for people living in the community

#### Employment

The level of employment in the general population was implemented using age and gender-specific prevalence figures from the US Bureau of Labor Statistics<sup>110</sup> Following these distributions most individuals stop working around the age of retirement (65 to 67 years) although some do stay employed. Because there is no age at which individuals must stop working, we assumed 70 as the age after which individuals would no longer be employed.

An US publication estimated the likelihood of employment in people with schizophrenia (OR 0.24, 95% CI 0.16 to 0.37) compared to individuals unaffected by schizophrenia, using data from the National Health Interview Survey.<sup>111</sup> This value was applied to the rates of employment in the general US population to estimate employment in the schizophrenia cohort. The likelihood of employment in people with remission or relapse was adjusted using rate ratios estimated from an analysis of US Adelphi data <sup>108</sup> (Table 11).

#### Caregiver consequences on employment

Informal caregivers were modelled uniquely to estimate the impact of weekly hours of informal care on labor participation. We assumed that caregivers would be mostly females (59.2%) have a mean age of 48.3 years.<sup>112</sup> Annual mortality used general US lifetables.<sup>79</sup> Informal caregivers' employment was conditional to age-specific probabilities of employment<sup>110</sup> In those predicted to work, the proportion of a full-time equivalent (FTE) in males and females was calculated using the equations below publication sourced from a Canadian publication.<sup>113</sup>

$Proportion_{FTEMales} = exp(-0.045Primary_{CG} - 0.032Care_{10} - 0.089Care_{15} - 0.156Care_{20})$	Equation 3
$Proportion_{FTE Females} = exp(-0.037 Primary_{CG} + 0.023 Care_{10} - 0.022 Care_{15} - 0.018 Care_{20})$	Fauation 4

Where *Primary*<sub>CG</sub> took the value of 1 for primary caregivers (assumed all were primary caregivers), and *Care*<sub>10</sub>, *Care*<sub>15</sub> and *Care*<sub>20</sub> took the value of 1 if informal care was provided for more than 10, 15 or 20 hours weekly, respectively, and took the value of 0 otherwise.

The proportion of individuals in the general US population having informal caregivers (15.6%) and the weekly average provision of informal care (10.0 hours) were informed by national US data.<sup>114</sup> Weekly hours of care in people with schizophrenia in remission and relapse was sourced from an analysis of US Adelphi data.<sup>108</sup>

#### Taxation

Direct taxes were calculated by multiplying gross income from employment (in people with schizophrenia, caregivers, and general population equivalents) by the US tax wedge (28.4%).<sup>115</sup> The tax wedge represents the amount of taxes and social security contributions related to a single worker. Taxes are paid by the employee and social security contributions are paid by the employee and employer. Indirect taxes were calculated by multiplying the consumption tax rate (10.1%) <sup>116</sup> by the disposable income of all individuals in the model. The rate of disposable income was calculated by dividing the average annual disposable income values by the average annual earnings from employment.<sup>117</sup> The resulting figure was used to estimate the share of individual's earnings or fiscal benefits spent on consumption and paid consumption taxes.

#### Legal involvement

Only a proportion of arrests result in individuals being incarcerated (66.0%).<sup>118</sup> We therefore implemented the number of people being arrested as 34.0% more than the individuals predicted by the model to be incarcerated.

#### **Disability benefits**

The proportion of people receiving Social Security Disability Insurance (SSDI), Supplemental Security Income (SSI) or both was informed by the Social Security administration (SSA) 2019 report.<sup>119</sup> We estimated that 6.6% of the entire schizophrenia population is a recipient of disability benefits, compared to 3.7% of the general US population. The age distribution of these recipients was also informed by SSA data.<sup>119</sup> In the absence of specific data we have assumed that people able to maintain a job would not be a recipient of SSA benefits. This is a simplification of reality as work incentives by the SSA enable employed individuals to still receive monthly financial support as well as Medicaid and Medicare services during a trial work period.<sup>120</sup>

#### Victimization

The likelihood of being victim of a crime in the general US population was modelled using data published by the US Department of Justice.<sup>121</sup> The relative risk of violent victimization in people with schizophrenia was obtained by dividing the annualized probability of violent victimization in people with schizophrenia <sup>122</sup> by the probability of violent victimization in the general population.<sup>121</sup>

#### Healthcare Insurance

Healthcare costs incurred by the US government were considered part of the fiscal expenses. In the general US population the proportion of individuals using publicly funded healthcare insurance was informed by US Census Bureau data.<sup>123</sup> In the schizophrenia population these parameters were sourced from an analysis of Medical Expenditures Panel Survey <sup>124</sup> suggesting most individuals with schizophrenia would use publicly funded healthcare insurances.<sup>125</sup>

#### 3.2. Fiscal consequences in incarcerated and homeless individuals

All individuals who were in prisons or jails incurred the costs of incarceration and were also assigned different healthcare costs than same age individuals living in the community. A similar approach was used for individuals who became homeless. An assumption was made that people who were homeless or incarcerated would use 100% publicly funded healthcare insurance. Ex-convicts and ex-homeless people were assumed to have the same rates of public healthcare financing than the remaining individuals living in the community.

Acronyms: OR, odds ratio; RR, relative risk; SE, standard error; SSDI, Social Security Disability Insurance; SSI, Supplemental Security Income; US, United States.

<sup>a</sup> Calculated by dividing the total number of beneficiaries excluding beneficiaries with schizophrenia by the total US population in 2019.

<sup>b</sup> Calculated by multiplying the total number of beneficiaries with schizophrenia or other psychotic disorder by 43.7% <sup>96</sup>, the share of schizophrenia as a proportion of other psychotic diseases.

<sup>c</sup> Calculated by dividing the estimated number of beneficiaries with schizophrenia by the total schizophrenia population in 2019.

<sup>d</sup> Ratio of the annualized probability of violent victimization in people with schizophrenia and the probability of violent victimization in the general US population.

#### Remission versus relapse

Table 11 depicts the inputs utilized to distinguish between individuals with symptoms of schizophrenia relapse versus remission.

Table 11 – Likelihood of social state transitions and fiscal consequences in people in remission and relapse

Description	Remission	Relapse	SE	Source
Social states				
Homeless/sheltered (rate ratio) <sup>a</sup>	0.30	1.47	[0.47], [0.22]	108
Arrests	0.70	2.36	[0.24], [0.28]	101
Fiscal consequences				
Any employment (rate ratio) <sup>a</sup>	1.66	0.55	[0.07], [0.10]	108
Has a caregiver (rate ratio)	0.42	1.40	[0.16], [0.13]	
Weekly hours of informal care	26.03	39.26	[3.64], [4.50]	
Victimization	0.87	1.33	[0.16], [0.24]	101

Acronyms: SE, standard error

<sup>a</sup> Rate ratios compare the likelihood of an event in people with schizophrenia in remission or relapse versus the general population of people with schizophrenia.

### 4. Fiscal costs and economic consequences

Membership to different social states determined the likelihood of economic consequences, as explained in the section above. The economic value of these consequences was sourced from peer reviewed or nationally US data and inflated to 2021 US dollars using the Consumer Price Index.<sup>127</sup> Table 12 summarizes the main inputs informing the monetary value of fiscal consequences and respective sources. Measures of variance for cost data were frequently not reported. We have therefore assumed that standard errors for these inputs would be 20% of the mean. This allowed estimating confidence intervals to be used in one-way sensitivity analysis.

Description	Inp	Source		
Average gross income from employment				
Age groups	Males	Females	128	
75+ Years	\$51,844	\$31,950		
65 to 74 years	\$67,958	\$41,096		
55 to 64 years	\$86,013	\$51,779		
45 to 54 years	\$91,329	\$60,186		
35 to 44 years	\$83,334	\$56,341		
25 to 34 years	\$57,014	\$44,767		
15 to 24 years	\$21,859	\$19,971		
Direct and indirect tax inputs				
Tax Wedge US	28	28.4%		
Disposable income	51	117		
Average tax in the US	10.1%		116	
Disability transfers				
Monthly SSDI	All beneficiaries	With schizophrenia <sup>b</sup>		
65+	\$1.389	\$1,089	119	

Table 12 – Monetary value of fiscal and economic consequences
